1. Primary syphilis
2. Hard chancre
3. In 2-3 weeks after syphilis infection, at the site where the infection (pale spirochetal) entered the body, there appears an external, hard lesion or blister – the hard chancre. The lesion is fairly painless and those infected rarely notice it. Nearby lymphatic nodes swell, but remain painless. Inside the hard chancre is the pale spirochetal. Infected individuals with the hard chancre can spread the disease.
4. Hard chancre on genital organs
5. Hard chancre on the breast
