1. Tertiary syphilis
2. Usually, before the fourth year of the disease, soft tumor-like balls (gummas) appear on the skin, bones, and internal organs. These tumors spread and turn into deep, long-lasting lesions. Lesions from gummas leave scars after healing. Infected individuals at this stage are not very contagious. Tertiary syphilis occurs only in those infected people who did not undergo treatment at all or failed to undergo treatment properly
3. Lesion from a gumma on the leg
4. Gummas of the forehead
