1. Gonorrhea

2. Gonorrhea in men is caused by the penetration of gonorrhoeae bacterium into the urethra. The first symptoms are discharge from the urethra and burning when urinating. They appear 3-4 days after infection. If treatment of gonorrhea starts early, it is usually cured in several weeks. If treatment starts late or does not start at all, gonorrhea becomes chronic. Chronic gonorrhea can be cured with proper treatment. Alcohol and sexual intercourse worsen the course of the disease. A past case of gonorrhea does not protect from subsequent infections.

3. Neisseria Gonorrhoeae. Gonorrhea is an infectious disease. It is caused by the gonorrhoeae microbe which was discovered in 1879 by the German scientists Neisser. When the bacterium touches the mucous membranes of the urinary canal, vagina, or uterus, it causes inflammation with pus. Discharge from the infected individual (pus, plasma) contain the bacterium and are contagious.

4. Gonorrhea in women is caused by the penetration of gonorrhoeae into the vagina or the urethra. Women infected with gonorrhea usually develop sores with pus and often have a burning sensation when urinating. When treatment starts early, gonorrhea in women is cured easily. Without proper treatment, women can develop serious consequences; the majority of women’s diseases are caused by gonorrhea. A mother infected with gonorrhea can infect the eyes of her child with gonorrhea during childbirth.
