1. Chancroid
2. Chancroid is an infectious disease; it is caused by a rod bacterium discovered in 1889 by the Belgian researcher Ducre. This microbe is present in the pus inside the chancre. Chancroid infects almost entirely through sexual intercourse. In 2-4 days after infection, at the site of infection, there appear one or several soft painful ulcers. A common complication of chancroid is the swelling of lymph nodes (buboes) that burst and develop painful, slow-healing ulcers.
With proper treatment, chancroid is cured without permanent health consequences
3. Rods of Ducre
4. Chancroid ulcer and buboe
